18.8 Fitting an ellipse to points in a plane. An ellipse in a plane can be described as the set of points

$$\hat{f}(t;\theta) = \begin{bmatrix} c_1 + r\cos(\alpha + t) + \delta\cos(\alpha - t) \\ c_2 + r\sin(\alpha + t) + \delta\sin(\alpha - t) \end{bmatrix}$$

where t ranges from 0 to 2π . The vector $\theta = (c_1, c_2, r, \delta, \alpha)$ contains five parameters, with geometrical meanings illustrated in figure 18.27. We consider the problem of fitting an ellipse to N points $x^{(1)}, \dots, x^{(N)}$ in a plane, as shown in figure 18.28. The circles show the N points. The short lines connect each point to the nearest point on the ellipse. We will fit the ellipse by minimizing the sum of the squared distances of the N points to the ellipse.

(a) The squared distance of a data point $x^{(i)}$ to the ellipse is the minimum of $\|\hat{f}(t^{(i)};\theta) - x^{(i)}\|^2$ over the scalar $t^{(i)}$. Minimizing the sum of the squared distances of the data points $x^{(1)}, \ldots, x^{(N)}$ to the ellipse is therefore equivalent to minimizing

$$\sum_{i=1}^{N} \|\hat{f}(t^{(i)}; \theta) - x^{(i)}\|^{2}$$

over $t^{(1)},\dots,t^{(N)}$ and θ . Formulate this as a nonlinear least squares problem. Give expressions for the derivatives of the residuals.

(b) Use the Levenberg–Marquardt algorithm to fit an ellipse to the 10 points:

$$(0.5,1.5),\quad (-0.3,0.6),\quad (1.0,1.8),\quad (-0.4,0.2),\quad (0.2,1.3)$$

$$(0.7, 0.1), (2.3, 0.8), (1.4, 0.5), (0.0, 0.2), (2.4, 1.7).$$

To select a starting point, you can choose parameters θ that describe a circle with radius one and center at the average of the data points, and initial values of $t^{(c)}$ that minimize the objective function for those initial values of θ .

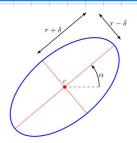

Figure 18.27 Ellipse with center (c_1,c_2) , and radii $r+\delta$ and $r-\delta$. The largest semi-axis makes an angle α with respect to horizontal.

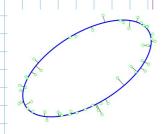

Figure 18.28 Ellipse fit to 50 points in a plane.

$$\hat{f}(t;\Theta) = [(1 + r \cos(d+t) + 8\cos(d-t)]$$

$$[(2 + r \sin(d+t) + 8\sin(d-t)]$$

$$\frac{\partial \hat{f}}{\partial c} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \frac{\partial \hat{f}}{\partial r} = \begin{bmatrix} \cos(a+t) \\ \sin(a+t) \end{bmatrix} \frac{\partial \hat{f}}{\partial =
$$10 \cos(a+t) \cos(a-t) - r\sin(a+t) - s\sin(a-t) - r\sin(a+t) + s\sin(a-t)$$

 $01 \sin(a+t) \sin(a-t) r\cos(a+t) + s\cos(a-t) r\cos(a+t) - s\cos(a-t)$

$$\hat{x} = x^{(n)} - (Df^T Df + x^{(h)} I)^{-1} Df^T \cdot f$$

$$D f(x^{(h)}) \quad \text{is} \quad 2\omega \times 15 \quad \text{matr:} x$$

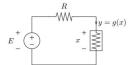

diagonals?

$$\frac{\left\| \int f(x^{(m)}) + \int f(x^{(m)}) +$$

So I couldn't fix this

$$f(x) = g(x) - (E - x)/R = 0.$$

The function g(x) gives the current through the nonlinear resistor as a function of the voltage x across its terminals.

Use Newton's method to find all the solutions of this nonlinear equation, assuming that $g(x)=x^3-6x^2+10x$. Consider three cases:

- (a) E = 5, R = 1.
- (b) E = 15, R = 3.
- (c) E = 4, R = 0.5.

Select suitable starting points by plotting f over the interval [0,4], and visually selecting a good starting point. You can terminate the Newton iteration when $|f(x^{(k)})| < 10^{-8}$. Compare the speed of convergence for the three problems, by plotting $|f(x^{(k)})|$ versus k, or by printing out $|f(x^{(k)})|$ at each iteration.

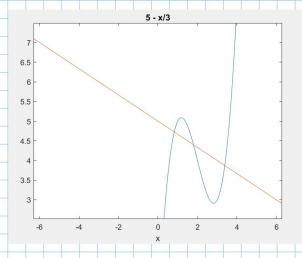

$$f(x) = g(x) - (E - x) = 0$$
 $y = g(x) - P g(x) = x^3 - 6x^2 + 10x$

$$\int_{\mathbb{R}} f(x) = x^3 - 6x^2 + 10x - (E - x) = x^3 - 6x^2 + 10x + \frac{x}{R} - \frac{E}{R}$$

From additional lecture notes

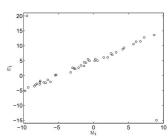

Compute
$$f(x)$$
 and $f'(x)$
 $f'(x) = 7x^2 - 12x + 10 + \frac{1}{R}$, $6 = 10^{-8}$

$$x^{+} = x - f(x) = x - x^{3} - 6x^{2} + 10x + x/R - E/R$$
 $f(x) = 3x^{2} - 12x + 10 + y/R$

13.2 The figure shows 42 data points (u_i, v_i) . The points are approximately on a straight line, except for the first and the last point.

The data are available in the file robappr.m as [u,v] = robappr;.

(a) Fit a straight line $v = \alpha + \beta u$ to the points by solving a least squares problem

minimize
$$g(\alpha, \beta) = \sum_{i=1}^{42} (\alpha + \beta u_i - v_i)^2$$
,

with variables α , β .

(b) Fit a straight line $v=\alpha+\beta u$ to the points by solving the unconstrained minimization problem

minimize
$$g(\alpha, \beta) = \sum_{i=1}^{42} \sqrt{(\alpha + \beta u_i - v_i)^2 + 25}$$

using Newton's method. Use as initial points the values of α and β computed in part (a). (With this starting point, no line search should be necessary; for other starting points, a line search may be needed.) Terminate the iteration when $\|\nabla g(\alpha, \beta)\| \le 10^{-6}$.

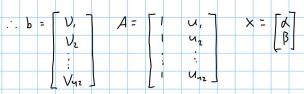

```
b) minimize g(a, \beta) = \frac{42}{2}\sqrt{(\lambda + \beta u)^2 + 25} from discussion (14-23)

g(x) = h(Cx+d) uz
